File # 20813

OFFICE OF CHIEF MEDICAL EXAMINER-CORONER

Date Sept. 8, 1965 Time 9:00 P.M.

I performed an autopsy on the body of DOROTHY DANDRIDGE

at CHIEF MEDICAL EXAMINER-CORONER'S MORTUARY, Hall of Justice, Los Angeles,

and from the anatomic findings and pertinent history I ascribe the death to:

ACUTE DRUG INTOXICATION.

DUE TO: INGESTION OF TOFRANIL.

(final Nov. 19, 1965)

ANATOMIC SUMMARY

SKELETAL SYSTEM:

1. Fractured right fifth metatarsal with ecchymosis of foot and ankle.

RESPIRATORY SYSTEM:

1. Focal pulmonary congestion.

CENTRAL NERVOUS SYSTEM:

1. Focal intravascular congestion of thalamus, basal ganglia, and pons.

GENITOURINARY SYSTEM:

1. Bilateral renal atrophy.
2. Bilateral ovarian cysts.

INTEGUMENTARY SYSTEM:

1. Old, healed, transverse scar of lower abdomen.
2. Old, healed scar of right subclavicular area.
3. Recent needle puncture of right buttock.

AUTOPSY FINDINGS

EXTERNAL EXAMINATION:

The unembalmed body is that of a Negro female reported as approximately 40 years of age, measuring 5'5" in length,

weighing 138 pounds, with black hair, brown eyes, and medium-dark olive complexion.

There is an old, healed, transverse scar of the lower abdomen.. There is a small, old, healed scar at the lateral margin of the right clavicle, as shown on Diagram #1 of the accompanying series of two diagrams. There is a recent needle puncture mark in the skin of the right buttock region (covered with an adhesive bandage) reportedly residual of a vitamin injection. Numerous loops of adhesive tape encircle the right foot and ankle in a "figure-8" bandage, and removal of the tape reveals a zone of blue-green to yellow-green ecchymosis of the right foot and ankle as shown on the diagram.

PRIMARY INCISION:

On opening the body the thoracic and abdominal viscera are in the usual position and relationships. The pleural and peritoneal surfaces are smooth and glistening, and free of adhesions. No excessive or unusual fluid is present in the body cavities.

ORGAN DESCRIPTION

HEART:

The heart is normal in size and contour, weighing 310 grams. The epicardial and internal pericardial surfaces are smooth and glistening and free of adhesions.

The aorta is virtually free of atherosclerosis throughout its length, with only a few small soft atheromatous plaques.

Dissection of the heart in the usual hemodynamic sequence reveals normal size and configuration of the cardiac chambers, great vessels and valves with no gross anatomic lesions or stigmata of disease, other than atherosclerosis.

The tricuspid, pulmonary, mitral and aortic valves measure 11.5, 7.0, 10.0 and 6.0 cm. in circuference respectively. The right and left ventricular walls measure 0.1 and 1.0 cm. in thickness respectively.

The coronary ostia are normal in size and position, and dissection of the coronary circulation reveals normal distribution and patency throughout all branches with only a small single atheromatous plaque just beyond the left coronary ostium

producing only minimal reduction of luminal diameter. No intraluminal thrombi or zones of hemorrhage into coronary artery wall are demonstrated. The myocardium, on section, appears normal without areas of fibrosis or infarction.

LUNGS:

The right and left lungs weigh 340 and 310 grams respectively. There is nodular distribution of increased firmness with small zones of intravascular congestion, but no areas of frankly suppurative pneumonitis or hemorrhage are apparent.

The pulmonary arteries and veins contain no grossly recognizable thrombi or emboli. The tracheobronchial tree is normal throughout. The larynx, hyoid bone and deep soft tissues of the neck show no indications of trauma.

LIVER:

This organ is slightly larger than usual, weighing 1720 grams, has smooth brown capsular surfaces and, on section, reveals intact lobular architecture. No localized lesions are evident. The gall bladder and biliary tree are grossly normal.

SPLEEN:

This organ weighs 50 grams, has smooth dark purple capsular surfaces and, on section, reveals intact splenic pulp of similar dark color.

PANCREAS:

The pancreas is normal externally and on section.

ADRENALS:

These glands are grossly intact.

KIDNEYS:

The kidneys are roughly equal in size and together weigh 240 grams. The capsular surfaces of the kidneys are primarily smooth and regular without major areas of cortical scarring or retraction. Section reveals moderate diffuse hypoplasia or atrophy with otherwise normal architecture of the cortex and medullary structures. The pelves, calyces, and ureters are grossly intact, as is the urinary bladder.

FILE # 20813
DOROTHY DANDRIDGE
Sept. 8, 1965

FEMALE REPRODUCTIVE SYSTEM:

The uterus is small and the cervix appears nulliparous. The right ovary contains a 1 1/2" in diameter dermoid cyst with hair and oily sebacious material. The left ovary contains a fluid-filled cyst. No anatomic lesions or marks of trauma are visible in the vagina or on the external genitalia.

GASTROINTESTINAL TRACT:

No gross abnormalities or anatomic lesions are demonstrated in any portion of the gastrointestinal tract. The stomach contains an estimated 150 cc. of non-descript liquid. No erosions, ulcerations, or hemorrhages are visible in the esophagus, stomach or duodenum. The appendix is grossly normal. The remainder of the small and large intestine is intact.

SKELETAL SYSTEM:

Except for the fractured fifth right metatarsal noted previously, no abnormalities or osseous lesions are demonstrated.

CENTRAL NERVOUS SYSTEM:

The head and scalp are normal externally. Reflection of the scalp reveals no subcutaneous, subaponeurotic, or temporalis muscle hemorrhage. The calvarium is normal externally and on removal permits escape of an average quantity of clear cerebrospinal fluid.

The brain is normal externally, weighing 1230 grams. The meninges are thin and translucent, showing no exudates or hemorrhages. The vessels about the base of the brain are normal in distribution and patency, without atheromatous plaques or intraluminal thrombi.

Sections through the cerebral hemispheres in the coronal plane reveal normal architecture throughout. The cerebellum, pons, medulla, and brain stem are grossly intact morphologically; however, many small caliber vessels (in the central white matter of the hemispheres and more conspiciously in the basal ganglia and pons) contain minute gelatinous thrombi, dilating the vascular lumen. No surrounding "ring hemorrhages" are evident.

Removal of the dura reveals no skull fracture, either in the calvarium or in the base of the cranial cavity. The foramen magnum and cervical spinal canal are grossly normal.

FILE # 20813
DOROTHY DANDRIDGE
Sept. 8, 1965

SPECIMENS:

Blood, liver, kidney, stomach, and contents for toxicology.

SECTIONS:

Selected sections for microscopic examination. Brain and lung for fat stain (frozen section). Routine tissue for hold.

HAROLD KADE, M.D.
DEPUTY MEDICAL EXAMINER

Sept. 20, 1965

COUNTY OF LOS ANGELES

OFFICE OF CHIEF MEDICAL EXAMINER-CORONER

#20813
DOROTHY DANDRIDGE
Autopsy: 9/8/65

MICROSCOPIC DESCRIPTION

FROZEN SECTIONS:

Lung and Brain reveal intravascular globules of fat staining material in two slides of lung tissue and two slides of brain tissue. There are several such foci on each slide.

HEART:

Aside from a few minute foci of mild degenerative change with associated inflammatory response, the myocardium is essentially intact.

LUNGS:

There is intravascular engorgement and dilatation by erythrocytes and amorphous proteinaceous material. The alveolar spaces show emphysematous dilatation in some areas; others contain a serous exudate.

LIVER:

There is marked congestive swelling of polygonal cells with virtual obliteration of sinusoids. There is focal portal chronic triaditis, but fatty droplets are minimal in number and sparsely distributed.

KIDNEYS:

There are chronic inflammatory and fibrotic changes involving both the glomerular and trabecular structures.

CENTRAL NERVOUS SYSTEM:

Sections reveal engorgement and dilatation of blood vessels with erythrocytes and pink-staining amorphous material. No

distinct zones of infarction or hemorrhage are evident.
